Yaniv Erlich
11:23 PM, May 12

Ady Ohad and Ofir: A really great and thorough job. You clearly understand the material and it seems that you had a lot of fun with this project. Excellent job. Grade: 100/100.

Exercise 1: Designing an mRNA vaccine against the south African variant

https://docs.google.com/document/d/1REzNz3VHjzsZ2iQVMg57RvN_nYjc5prMMER2h5eaCoM/edit

Hello! You were recruited by the Pfizer/BioNTech Bioinformatics team. As you know, the vaccine operation is going great but we are concerned that the vaccine is not working well for the South African variant. Your mission is to update the mRNA vaccine based on the South African Spike!

Prerequisites

Get Started 5

Install the BioPython package.

```
!pip install biopython
```

```
Requirement already satisfied: biopython in /usr/local/lib/python3.7/dist-packages (1.78)
Requirement already satisfied: numpy in /usr/local/lib/python3.7/dist-packages (from biopython) (1.19.5)
```

```
!pip install iso3166
```

```
Requirement already satisfied: iso3166 in /usr/local/lib/python3.7/dist-packages (1.0.1)
```

```
from collections import Counter, defaultdict
import re
from datetime import datetime

import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import lxml.etree as ET

from Bio import Entrez, SeqIO, Seq
from Bio.SeqUtils import GC
from Bio import Seq

from iso3166 import countries
```

Step 2

Download the mRNA design of the Pfizer and Moderna vaccines from: https://github.com/NAalytics/Assemblies-of-putative-SARS-CoV2-spike-encoding-mRNA-sequences-for-vaccines-BNT-162b2-and-mRNA-1273

```
!git clone https://github.com/NAalytics/Assemblies-of-putative-SARS-CoV2-spike-encoding-mRNA-sequences-for-vaccines-BNT-162b2-a
```

```
fatal: destination path 'Assemblies-of-putative-SARS-CoV2-spike-encoding-mRNA-sequences-for-vaccines-BNT-162b2-and-mRNA-1273' al
```

```
!ls Assemblies-of-putative-SARS-CoV2-spike-encoding-mRNA-sequences-for-vaccines-BNT-162b2-and-mRNA-1273
```

```
'Assemblies of putative SARS-CoV2-spike-encoding mRNA sequences for vaccines BNT-162b2 and mRNA-1273.docx.pdf'
 Figure1Figure2_032321.fasta
```

```
README.md
```

```
mRNA_pfizer_moderna_vaccine_designs_filepath = \
    'Assemblies-of-putative-SARS-CoV2-spike-encoding-mRNA-sequences-for-vaccines-BNT-162b2-and-mRNA-1273/Figure1Figure2_032321.f
```

```
for record in SeqIO.parse(mRNA_pfizer_moderna_vaccine_designs_filepath, "fasta"):
    print(record)
    print('---------')
```

```
ID: Figure1_032321_Spike-encoding_contig_assembled_from_BioNTech/Pfizer_BNT-162b2_vaccine
Name: Figure1_032321_Spike-encoding_contig_assembled_from_BioNTech/Pfizer_BNT-162b2_vaccine
Description: Figure1_032321_Spike-encoding_contig_assembled_from_BioNTech/Pfizer_BNT-162b2_vaccine
Number of features: 0
Seq('GAGAATAAACTAGTATTCTTCTGGTCCCCACAGACTCAGAGAGAACCCGCCACC...GCA')
---------
ID: Figure_2_32321_Spike-encoding_contig_assembled_from_Moderna_mRNA-1273_vaccine
Name: Figure_2_32321_Spike-encoding_contig_assembled_from_Moderna_mRNA-1273_vaccine
Description: Figure_2_32321_Spike-encoding_contig_assembled_from_Moderna_mRNA-1273_vaccine
Number of features: 0
Seq('GGGAAATAAGAGAGAAAAGAAGAGTAAGAAGAAATATAAGACCCCGGCGCCGCC...AAA')
---------
```

```
vaccines_mRNA_seq = {}

for record in SeqIO.parse(mRNA_pfizer_moderna_vaccine_designs_filepath, "fasta"):
    # The sequences are actually DNA, so we need to first transcribe them to get the RNA seq.
    vaccines_mRNA_seq[re.search('Moderna|BioNTech[^_]*', record.id)[0]] = record.seq.transcribe()

vaccines_mRNA_seq
```

```
{'BioNTech/Pfizer': Seq('GAGAAUAAACUAGUAUUCUUCUGGUCCCCACAGACUCAGAGAGAACCCGCCACC...GCA'),
 'Moderna': Seq('GGGAAAUAAGAGAGAAAAGAAGAGUAAGAAGAAAUAUAAGACCCCGGCGCCGCC...AAA')}
```

```
len(vaccines_mRNA_seq['BioNTech/Pfizer']), len(vaccines_mRNA_seq['Moderna'])
```

```
(4175, 4004)
```

Step 3

Download the sequence of “Wuhan” SARS-CoV-2 sequence from NCBI Genbank accession number NC_045512.2

```
def get_genome(id):
    # this function downloads a genome from the NBCI database (seen in lecture 2)
    handle = Entrez.efetch(db='nucleotide', id=id, rettype='gb', retmode='text', email='no@one.com')
```

```
    genome = SeqIO.read(handle, 'genbank')

    return genome

wuhan_sars_cov_2_sequence = get_genome('NC_045512.2')

print(wuhan_sars_cov_2_sequence.name)
print(wuhan_sars_cov_2_sequence.description)
# print(wuhan_sars_cov_2_sequence.seq)
```

```
NC_045512
Severe acute respiratory syndrome coronavirus 2 isolate Wuhan-Hu-1, complete genome
```

Step 4

The NCBI Virus database (https://www.ncbi.nlm.nih.gov/labs/virus/vssi/#/) has over 85,000 complete sequences of SARS-CoV-2. Download all complete sequences of SARS-CoV-2 in a FASTA format (You don't need these sequences until question #15)

Used the following page to search and find (complete) variants, and (manually) download them in FASTA format, to be uploaded to gDrive:

https://www.ncbi.nlm.nih.gov/labs/virus/vssi/#/virus?SeqType_s=Nucleotide&VirusLineage_ss=Severe%20acute%20respiratory%20syndrome%20coronavirus%202,%20taxid:2697049&Completeness_s=complete&HostLineage_ss=Homo%20sapiens%20(human),%20taxid:9606

Questions

Basics:

Yaniv Erlich
11:02 PM, May 12

Very nice. Correct.

1

Create a function that takes mRNA as an input and returns the translated coding region (Hint 1: you need to find the initiation codon and the stop codon. Hint 2: use BioPython!).

```
def get_translated_region(mRNA_seq, start_codons=['AUG'], end_codons=['UGA', 'UAA', 'UAG'], include_start_codon=True, include_e
    if not isinstance(mRNA_seq, str):
        mRNA_seq = str(mRNA_seq)

    coding_region_match = re.search(rf'(?:.{{3}})*?((?:{"|".join(start_codons)})(?:.{{3}})*?(?:{"|".join(end_codons)}))', mRNA_

    if coding_region_match is None:
        raise IndexError('Either the start codon or any of the end codons were not found in the mRNA sequence.')

    translated_seq = Seq.Seq(coding_region_match[1]).translate()
    if not include_start_codon:
        translated_seq = translated_seq[1:]
    if not include_end_codon:
        translated_seq = translated_seq[:-1]

    start_idx = re.search(rf'(?:.{{3}})*?((?:{"|".join(start_codons)}))', mRNA_seq).span()[1] - 3
    end_idx = start_idx + len(coding_region_match[1]) - 3

    actual_end_codon = coding_region_match[1][-3:]

    return {
        'Amino Seq': translated_seq,
        'Nucleotide Seq': coding_region_match[1],
        'End Codon': actual_end_codon,
        'Start Codon Index': start_idx,
        'End Codon Index': end_idx
    }
```

```
vaccines_data = {company_name: get_translated_region(vaccines_mRNA_seq[company_name]) for company_name in vaccines_mRNA_seq}

for company_name in vaccines_data:
    print(f'{company_name}:\n======================')
    for key in vaccines_data[company_name]:
        if 'Seq' not in key:
            print(f'- {key}: {vaccines_data[company_name][key]}')
    print(f'- Length of the coding sequence is {len(vaccines_data[company_name]["Nucleotide Seq"]) - 3} nucleotides ({len(vacci
    print()
```

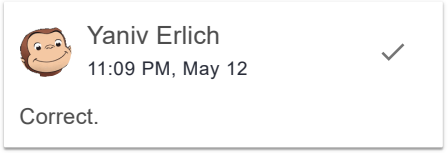
```
BioNTech/Pfizer:
=======================
- End Codon: UGA
- Start Codon Index: 54
- End Codon Index: 3873
- Length of the coding sequence is 3819 nucleotides (1273 amino acids), including the start codon but excluding the end codon.

Moderna:
=======================
- End Codon: UGA
- Start Codon Index: 57
- End Codon Index: 3876
- Length of the coding sequence is 3819 nucleotides (1273 amino acids), including the start codon but excluding the end codon.
```

2

For each vaccine:

1. What's the position of the initiation codon ("AUG")? (All positions should be reported as zero based)
2. What's the position of the termination codon?
3. What sequence did each company use for the stop codon?
4. Please suggest another stop codon sequence.
5. How would you call the area between the first nucleotide and the "AUG" site?
6. How would you call the area between the termination codon and the last nucleotide?



BioNTech/Pfizer:

1. Start Codon Index: 54 (0 based)
2. End Codon Index: 3876
3. End Codon: UGA

Moderna:

1. Start Codon Index: 57 (0 based)
2. End Codon Index: 3879
3. End Codon: UGA

Both:

4. Other possible end codon sequences are: **UAA**, **UAG**.
5. The area between the first nucleotide and the **AUG** site is called the 5' UTR (untraslated region).
6. The area between the termination codon and the last nucleotide is called the 3' UTR (untraslated region).

3

Using your function, translate the coding area into protein. What's the length of each coding sequence?

```
# for company_name in vaccines_data:
#     print(company_name)
#     print(f'Translates coding area into protein: {vaccines_data[company_name]["Amino Seq"]}:\n======================')
```

Yaniv Erlich
11:09 PM, May 12

Correct.

BioNTech/Pfizer:

- Length of the coding sequence is 3819 nucleotides (1273 amino acids), including the start codon but excluding the end codon.

Moderna:

- Length of the coding sequence is 3819 nucleotides (1273 amino acids), including the start codon but excluding the end codon.

4

Are the coding regions of the vaccines identical in the protein level?

```
company_names = list(vaccines_data.keys())
company_names
```

```
['BioNTech/Pfizer', 'Moderna']
```

```
vaccines_data[company_names[0]]['Amino Seq'] == vaccines_data[company_names[1]]['Amino Seq']
```

```
True
```

Yaniv Erlich
11:09 PM, May 12
Correct

The coding regions of the vaccines **are identical** on the **protein** level.

5

Are the coding regions of the vaccines identical in the nucleotide level?

Yaniv Erlich
11:09 PM, May 12
Correct

```
vaccines_data[company_names[0]]['Nucleotide Seq'] == vaccines_data[company_names[1]]['Nucleotide Seq']
```

```
False
```

The coding regions of the vaccines are **NOT identical** on the **nucleotide** level.

##**Codon usage**:

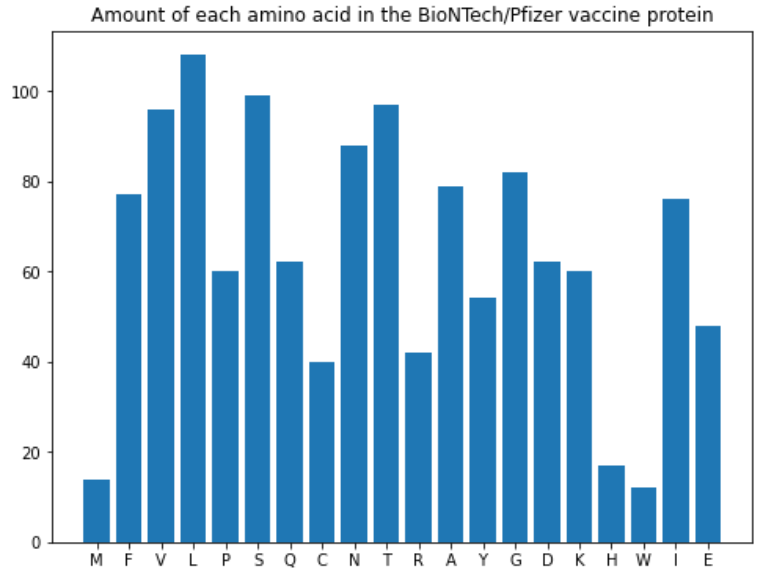
6

Create a histogram of amino-acids usage for the Pfizer vaccine

```
amino_counter = Counter(str(vaccines_data[company_names[0]]['Amino Seq']))

plt.figure(figsize=(8, 6))
plt.bar(amino_counter.keys(), amino_counter.values())
plt.title(f'Amount of each amino acid in the {company_names[0]} vaccine protein');
```

Yaniv Erlich
11:09 PM, May 12
Correct



7

Create the same histogram but color each codon within the amino-acid (i.e. create a stacked histogram)

```
nucleotide_seq = str(vaccines_data[company_names[0]]['Nucleotide Seq'])

amino_nucleotide_counter = defaultdict(lambda: defaultdict(int))
for amino_idx, amino in enumerate(str(vaccines_data[company_names[0]]['Amino Seq'])):
    for codon_sub_idx in range(3):
        amino_nucleotide_counter[amino][nucleotide_seq[(amino_idx * 3) + codon_sub_idx]] += 1

amino_nucleotide_counter
```

```
defaultdict(<function __main__.<lambda>>,
            {'A': defaultdict(int, {'A': 4, 'C': 144, 'G': 79, 'U': 10}),
             'C': defaultdict(int, {'C': 27, 'G': 40, 'U': 53}),
             'D': defaultdict(int, {'A': 62, 'C': 44, 'G': 62, 'U': 18}),
             'E': defaultdict(int, {'A': 62, 'G': 82}),
             'F': defaultdict(int, {'C': 62, 'U': 169}),
             'G': defaultdict(int, {'A': 12, 'C': 66, 'G': 167, 'U': 1}),
             'H': defaultdict(int, {'A': 17, 'C': 32, 'U': 2}),
             'I': defaultdict(int, {'A': 76, 'C': 66, 'U': 86}),
             'K': defaultdict(int, {'A': 129, 'G': 51}),
             'L': defaultdict(int, {'C': 111, 'G': 105, 'U': 108}),
             'M': defaultdict(int, {'A': 14, 'G': 14, 'U': 14}),
             'N': defaultdict(int, {'A': 176, 'C': 67, 'U': 21}),
             'P': defaultdict(int, {'A': 4, 'C': 146, 'U': 30}),
             'Q': defaultdict(int, {'A': 66, 'C': 62, 'G': 58}),
```

```
            'R': defaultdict(int, {'A': 43, 'C': 21, 'G': 62}),
            'S': defaultdict(int, {'A': 64, 'C': 121, 'G': 64, 'U': 48}),
            'T': defaultdict(int, {'A': 131, 'C': 160}),
            'V': defaultdict(int, {'C': 8, 'G': 183, 'U': 97}),
            'W': defaultdict(int, {'G': 24, 'U': 12}),
            'Y': defaultdict(int, {'A': 54, 'C': 49, 'U': 59})})
```

```
df = pd.DataFrame(amino_nucleotide_counter)
df
```

	M	F	V	L	P	S	Q	C	N	T	R	A	Y	G	D	K	H	W	I	E
A	14.0	NaN	NaN	NaN	4.0	64	66.0	NaN	176.0	131.0	43.0	4	54.0	12	62	129.0	17.0	NaN	76.0	62.0

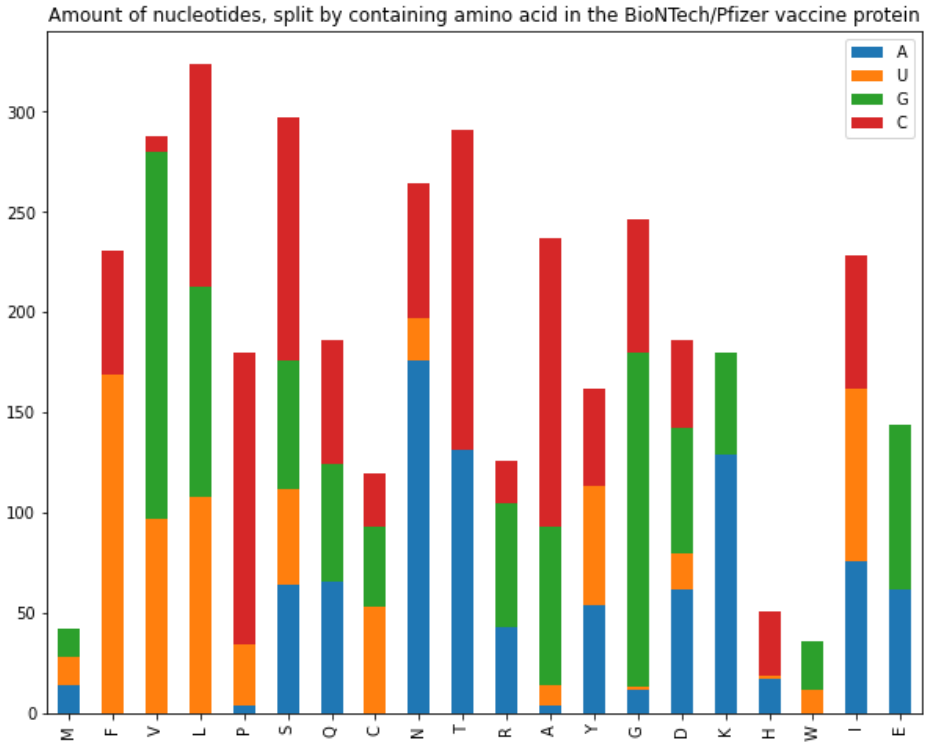
Yaniv Erlich
11:10 PM, May 12

Hmm... That was not the question. You created a histogram of the nucleotides but the question was about *codons*
-5pt

```
df.transpose().plot(kind="bar", stacked=True, figsize=(10, 8))
plt.title(f'Amount of nucleotides, split by containing amino acid in the {company_names[0]} vaccine protein');
```



Comparison to the Wuhan strain:

8

What's the length of the Wuhan strain genome?

```
print(f'The length of the Wuhan strain genome is {len(wuhan_sars_cov_2_sequence.seq)} nucleotides.')
```

```
The length of the Wuhan strain genome is 29903 nucleotides.
```

Yaniv Erlich
11:10 PM, May 12

Correct

9

Report the nucleotide sequence of the Spike region of the Wuhan strain from the initiation codon to the termination codon (hint: use the information in the NCBI website about the starting and stopping position of Spike)

```
# From https://www.ncbi.nlm.nih.gov/gene/43740568
wuhan_sars_cov_2_data = get_translated_region(str(wuhan_sars_cov_2_sequence.seq[21563 - 1: 25384].transcribe()))
```

```
# Number of characters to print per row
step = 102

for start_idx in range(0, len(wuhan_sars_cov_2_data['Nucleotide Seq']), step):
    print(wuhan_sars_cov_2_data['Nucleotide Seq'][start_idx:start_idx + step])
```

```
AUGUUUGUUUUUCUUGUUUUAUUGCCACUAGUCUCUAGUCAGUGUGUUAAUCUUACAACCAGAACUCAAUUACCCCCUGCAUACACUAAUUCUUUCACACGU

```

Yaniv Erlich
11:12 PM, May 12

Correct. As a side comment: it is a bad practice to encode positions as constants and not variables. You would look at this code in one year, you will not even remember what it means. So a better solution is to say:

spike_start = 21563
spike_end = 25384
and use those variables to get the sequence (edited)

```

```
len(wuhan_sars_cov_2_data['Nucleotide Seq'])
```

```
3822
```

10

Report the GC content of the Spike region of the Wuhan strain and compare it to the GC content of the Spike region of the Pfizer vaccine

```
# [Ady - Note]: Changed this on Fri morning (before 11:30) when I noticed we had a mistake here
# (we previously looked at the entire virus instead of just the spike and got a GC content of 37.97%)
f'Wuhan virus variant spike protein GC content is: {GC(wuhan_sars_cov_2_data["Nucleotide Seq"]):.2f}%.'
```

```
'Wuhan virus variant spike protein GC content is: 37.31%.'
```

```
f'{company_names[0]} vaccine (spike protein) GC content is: {GC(vaccines_data[company_names[0]]["Nucleotide Seq"]):.2f}%.'
```

```
'BioNTech/Pfizer vaccine (spike protein) GC content is: 56.99%.'
```

Yaniv Erlich
11:13 PM, May 12

Correct.

11

Translate the sequence into amino acids and report the sequence of the protein

```
step = 68
for start_idx in range(0, len(wuhan_sars_cov_2_data['Amino Seq']), step):
    print(wuhan_sars_cov_2_data['Amino Seq'][start_idx:start_idx + step])
```

```

Compare between the Spike region of the Pfizer vaccine to the Spike of the Wuhan strain in the protein level.

Are there any differences and where?

Bonus: explain the differences!

```
print('Vac: Pfizer vaccine  -  Vir: Wuhan variant virus\n==========================================================================\n')
step = 68
for start_idx in range(0, len(vaccines_data[company_names[0]]['Amino Seq']), step):
    vac_part = vaccines_data[company_names[0]]['Amino Seq'][start_idx:start_idx + step]
    vir_part = wuhan_sars_cov_2_data['Amino Seq'][start_idx:start_idx + step]

    print('Vac:', vac_part)
    print('Vir:', vir_part)
    print('    ', "".join([' ' if vac_part[i] == vir_part[i] else '^' for i in range(len(vac_part))]))
```

Yaniv Erlich
11:13 PM, May 12

Correct and a nice presentation.

```

The **PP** amino change in the virus is put there to keep the structural integrity of the spike protein, and not allow it to "transform" from its "attach to cell" form.

Based on: https://cen.acs.org/pharmaceuticals/vaccines/tiny-tweak-behind-COVID-19/98/i38

"... Once attached, the spike undergoes a dramatic transformation, stretching before partially turning inside out to forcefully fuse with our cells. ..."

"... Unfortunately for vaccine developers, spike proteins are liable to spring from their stubby prefusion shape into their elongated postfusion form on a hair trigger. ..."

"... adding two prolines—the most rigid of the 20 amino acids—to a key joint of a vaccine's spike protein could stabilize the structure's prefusion shape. This 2P mutation worked in preclinical studies of Graham and Moderna's MERS vaccine, so they applied it to Moderna's COVID-19 vaccine. ..."

"... Other companies, including Johnson & Johnson, Novavax, and Pfizer, are hoping the 2P mutation works for their COVID-19 vaccines too. ..."

13

For the amino acids that appear in the vaccine and the Wuhan strain, create a look-up table that maps between the Wuhan strain codon to the Pfizer codon

We build something that is a bit more than a LUT: we count *how many times* each codon in the vaccine was used instead of the corresponding codon in the virus.

```
vir_to_vac_codons_map = defaultdict(lambda: defaultdict(int))
```

```
for start_idx in range(0, len(vaccines_data[company_names[0]]['Amino Seq'])):
    vac_amino = vaccines_data[company_names[0]]['Amino Seq'][start_idx]
    vir_amino = wuhan_sars_cov_2_data['Amino Seq'][start_idx]

    if vac_amino == vir_amino:
        vac_codon = vaccines_data[company_names[0]]['Nucleotide Seq'][start_idx * 3:(start_idx + 1) * 3]
        vir_codon = wuhan_sars_cov_2_data['Nucleotide Seq'][start_idx * 3:(start_idx + 1) * 3]

        vir_to_vac_codons_map[vir_codon][vac_codon] += 1
```

```
vir_to_vac_codons_map
```

```
defaultdict(<function __main__.<lambda>>,

```

14

Can you deduce any rule about the look-up table that Pfizer uses internally?

Bonus: explain the differences!

Yaniv Erlich
11:15 PM, May 12

Question is correct but bonus is not. The increased GC content is for better translation efficiency and not double helix (RNA is a single strand).

It looks like most codons in the virus were replaced (in the vaccine) with compatible codons, but with more G and C nucleotides in them.

A few examples:

- 'AAA' was mapped to 'AAG' in more than 80% of the cases.
- 'AAU' was mapped to 'AAC' in more than 75% of the cases.
- 'AUU' was mapped to 'AUC' in more than 85% of the cases.
- 'CAA' was mapped to 'CAG' in more than 90% of the cases.
- 'UUG' was mapped to 'CAC' or 'CUG in 100% of the cases.

There are also cases that are less pronounced (e.g. 'ACU' to 'ACC' in only ~55%), and even cases where a mapping reduced the GC content (e.g. 'GGG' to 'GGA' in 66%), but both of these are the minority of cases (especially taking into account the codon counts).

This leads to an overall increase in GC content (as also seen above in question 10).

Main understanding of what a higher GC content does in this case:

Contrary to the fact the a higher GC content makes double-helix DNA more structurally sound, a higher GC content in this RNA sequence actually makes the virus weaker or "less fit" by making it less able to bind to host cells through the ACE2 protein.

Overall it looks like researchers are trying to balance having a more sound structure of the spike protein (using the **PP** change in the amino sequence), with making the virus more easy to defend against by the immune system using the different codons (which also leads to a higher GC content).

Based on: https://www.nature.com/articles/s41598-020-72533-2

"... Understanding the mechanism that leads to viral attenuation requires a thorough characterization of the viral sequence and of the consequences of sequence changes. There are several factors that may contribute to the efficacy of deoptimization strategies. In changing the codon pair usage, the dinucleotide frequency and the GC content are altered; mRNA secondary structure and translational kinetics are also perturbed. Further, the CpG content is changing, leading potentially to altered immunogenicity. It is likely that codon pair (or codon) deoptimization leads to reduced expression, either due to changes in transcription, mRNA stability, or translation efficiency[45,46]. Alternatively, it is possible that deoptimization may lead to perturbed cotranslational folding[47], resulting in altered protein conformation. In the case of the S protein, this may lead to decreased binding affinity for the ACE2 protein, thus affecting viral fitness. ..."

And this is for the ACE2 protein:

https://theconversation.com/what-is-the-ace2-receptor-how-is-it-connected-to-coronavirus-and-why-might-it-be-key-to-treating-covid-19-the-experts-explain-136928

The South-African Variant (B.1.351):

15

The 75,000 genomes that you have are NOT aligned to the Wuhan strain.

For example:

Notice that a nucleotide 13th in the genome Wuhan strain corresponds to nucleotide 14th in the genome in your collection. So you cannot simply use positions from the Wuhan strain to find positions in your collection.

Unfortunately, the only information that you have about the South Afircan variant is based on the Wuhan coordinates.

Namely, you know that (i) position 23011 in Wuhan strain is not “G” but “A” and (ii) position 23062 is not “A” but “T” (iii) and that position 21800 is not “A” but “C”.

Without aligning, develop an algorithm to quickly sift through the 75000 genomes and find all entries that can match the South Afircan variant (hint: mutations occur very rarely. You can assume that positions adjacent to the mutated sites are identical to the Wuhan strain).

Our algorithm will work in the following manner:

- We will look at a search area around the mutation site (as indexed by the Wuhan variant); e.g. if the mutation site is at 21800 in the Wuhan variant, we will look at the area 21700 - 21900 in the tested sample.
- In that area we will search for a sequence that includes the mutation; e.g. if we look at 5 nucleotides on each side of the mutation site for site 21800, in the Wuhan varinat we have "GTTTG**A**TAACC", so we will be searching for "GTTTG**C**TAACC" in the search area of the sample.
- We will do this for several search area sizes and several searched sequence lengths, to be able to better select the appropriate values or these.

- We will be assuming throught the above, that it is not necessary to work in tripletes of codons, as the chances for a problem to arise from these are low (we will however verify that our results make sense, by comparing between the different findings).

"20__100" is a subsample of "5__300": True
"10__300" is a subsample of "5__300": True
"10__200" is a subsample of "5__300": True
"10__100" is a subsample of "5__300": True
"5__300" is a subsample of "5__300": True
```

```
"5__200" is a subsample of "5__300": True
"5__100" is a subsample of "5__300": True
```

- We found there are 64 such samples, if we require to find a nucleotide sequence of length 21 (or less), within an area of 201 nucleotides (or more).
- Searching for longer sequences (especially when the search area is on the smaller side) would result in less sequences found (but a subset of the 64 sample we found, not different ones). **Note**: This means there's at least one other mutation/sequencing error between 20 and 50 nucleotides away from one of the existing mutation sites, or that there's a large "misalignment" that prevents finding the requested sequence in the search area.

Yaniv Erlich

Correct.

16

Report all entries in your collection that you think match the South Afican variant. Where were they collected? Does it make sense?

```

There are no samples that could not be classified by country, but for 2 samples from the UK we have no collection date.

We will not ignore these 2 samples, just to be on the safe side (as we have no info supporting we could ignore them).

The results make sense because:

1. All of the samples were found during 2021, after the SA variant has been identified to exist (with the exception of the 2 samples from the UK, for which we don't know the collection date).
2. None of the SA variant samples were found in China.
3. Some were found in Ghana.
4. Many were found in the US where the variant has been spotted according to news. Many were spotted there (presumably) due to more availability of sequencing technologies near by.

We would actually expect to find more in Ghana (or other African countries), however we presume this is not the case due to the lack of availability of sequencing technologies in that region of the world, combined with the difficulty of transporting samples to the US for sequencing.

In the following section we will actually cull some samples based on their protein structure.

17

Develop a method to extract the Spike sequence of one of the entries, translate, and report the protein sequence (hint: the South African spike is not very different than the Wuhan strain and must start with AUG)

We will use the start of the spike protein from the Wuhan variant to find the beginning of the SA variant's spike protein.

```
# We use the Wuhan variant's spike protein start that we have from a previous question.
```

```
spike_protein_nt_start = 'AUGUUUGUUUUUCUUGUUUUAUUGCCACUAGUCUCUAGUCAGUGUGUUAAUCUUACAACCAGAACUCAAUUACCCCCUGCAUACACUAAUUCUUUCACACGU
```

```
for sample_id in complete_covid_sa_sequences:
    finds = re.findall(spike_protein_nt_start, str(complete_covid_sa_sequences[sample_id].seq.transcribe()))
    print(sample_id, len(finds))
```

Trying to use the long sequence above doesn't yield a result for every sample (meaning we didn't find the spike start in every sample that we marked as belonging to the SA variant, probably due to more mutations/sequencing errors).

We'll try a shorter match.

```
spike_protein_nt_start = 'AUGUUUGUUUUUCUUGUUUUAUUGCCACUAGUCU'
```

```
for sample_id in complete_covid_sa_sequences:
    finds = re.findall(spike_protein_nt_start, str(complete_covid_sa_sequences[sample_id].seq.transcribe()))
    print(sample_id, len(finds))

This yields exactly one match per sample, so we can use this to identify the protein start.

We will use this to get the spike protein for each of the samples we marked as the SA variant.

```
# Map between sample id and spike protein sequence.
sa_spike_proteins = {}
for sample_id in complete_covid_sa_sequences:
    sample_spike_start = re.search(spike_protein_nt_start, str(complete_covid_sa_sequences[sample_id].seq.transcribe())).span()
    sa_spike_proteins[sample_id] = get_translated_region(complete_covid_sa_sequences[sample_id].seq.transcribe()[sample_spike_st
```

Let's have a look at all the end codons of all the samples.

Perhaps we can find a distinction between the SA and Wuhan variants based on that?

```
set([d['End Codon'] for d in sa_spike_proteins.values()])
```

```
{'UAA'}
```

As all the samples have the same end codon, we can't distinguish between the variants based on them.

```
# Reverse map between the spike protein sequence and the sample ids that correspond to it.
unique_sa_spike_proteins = defaultdict(list)
for sample_id in sa_spike_proteins:
    unique_sa_spike_proteins[str(sa_spike_proteins[sample_id]['Amino Seq'])].append(sample_id)

# Histogram proteins explain how many samples each.
number_of_samples_per_unique_sa_spike_protein_hist = defaultdict(int)

# Unique spike proteins that don't contain coding ambiguity (that is marked by a non existing 'X' amino).
unique_sa_spike_proteins_without_coding_ambiguity = []
culled_sa_spike_proteins = []

for unique_sa_spike_protein in unique_sa_spike_proteins:
    number_of_samples_per_unique_sa_spike_protein_hist[len(unique_sa_spike_proteins[unique_sa_spike_protein])] += 1

    # According to: https://www.genome.jp/kegg/catalog/codes1.html
    if 'X' not in unique_sa_spike_protein and 'B' not in unique_sa_spike_protein \
        and 'Z' not in unique_sa_spike_protein and 'J' not in unique_sa_spike_protein:
        unique_sa_spike_proteins_without_coding_ambiguity.append(unique_sa_spike_protein)
    else:
        culled_sa_spike_proteins.append(unique_sa_spike_protein)

number_of_samples_per_unique_sa_spike_protein_hist
```

```
defaultdict(int, {1: 26, 2: 3, 3: 2, 8: 1, 18: 1})
```

```
len(unique_sa_spike_proteins), len(unique_sa_spike_proteins_without_coding_ambiguity)
```

```
(33, 10)
```

We found that our 64 samples, are described by a total of 33 different spike proteins, and more specifically:

- 18 of the samples are described by one protein.

- 8 of the samples are described by a different protein.
- 6 of the samples are described by 2 other different proteins (each describes 3 samples).
- 6 of the samples are described by 3 other different proteins (each protein describing a pair of samples).
- And 26 samples are described by a unique protein.

Then, we cull samples that have amino coding ambiguities (that have any of the non-existing **X, B, J, Z** aminos in the translated amino sequence), and when we look at the number of unique spike proteins left to analyze, we remain with 10.

We could have still used these samples while ignoring only the non-existing aminos instead of the entrire sample, however in the following section we will be using majority-vote (to decide which amino the SA variant virus' spike protein has in cases of disagreement between the samples), and using part of the sequence would mean the majority vote would be based on a different number of "voters" per amino acid.

We will however look at the proteins we culled as well (in a dedicated sub-section at the end of this section), and see if taking them into account produces different results.

The following **35** samples are used (divided by their spike proteins):

```
sorted_samples = sorted(
    {protein: samples for protein, samples in unique_sa_spike_proteins.items() if protein in unique_sa_spike_proteins_without_c
    key=lambda x: len(x[1]), reverse=True)

for country, samples in sorted_samples:
    for start_idx in range(0, len(samples), 5):
        print(", ".join(samples[start_idx:start_idx + 5]))
    print()

```

We see that while most proteins agree in most cases on the amino level, one protein is "vastly" different. Actually, it contains a **LAL** amino sequence that the other samples don't, so we will try to "move" the other sequences by 3 aminos at that point to see how similar the proteins are then.

```
different_amino_seq = 'LALHRSYLTPGDSSSGW'
regular_amino_seq = 'HRSYLTPGDSSSGW'

unique_moved_sa_spike_proteins_without_coding_ambiguity = []

for s in unique_sa_spike_proteins_without_coding_ambiguity:
    if s.find(different_amino_seq) != -1:
        unique_moved_sa_spike_proteins_without_coding_ambiguity.append(s)
        weird_sa_spike_proteins_without_coding_ambiguity = s
    else:
        difference_start = s.find(regular_amino_seq)
        unique_moved_sa_spike_proteins_without_coding_ambiguity.append(f'{s[:difference_start]}   {s[difference_start:]}')

s1 = unique_sa_spike_proteins_without_coding_ambiguity[0]

step = 136
for start_idx in range(0, len(s1), step):
    for s in unique_moved_sa_spike_proteins_without_coding_ambiguity:
        print(s[start_idx:start_idx + step])

    s_parts = [s[start_idx:start_idx + step] for s in unique_moved_sa_spike_proteins_without_coding_ambiguity]
    s_is = [set([s_part[i] for s_part in s_parts]) for i in range(len(s_parts[0]))]
    comparison = [' ' if len(s_i) == 1 else '^' for s_i in s_is]
    print("".join(comparison))
```

```

```
wuhan_sars_cov_2_data['Amino Seq'].find(different_amino_seq)
```

```
241
```

```
unique_sa_spike_proteins[weird_sa_spike_proteins_without_coding_ambiguity]
```

```
['MW763124.1']
```

We see that now the proteins are much more similar.

On closer inspection, we find that:

1. There is only one sample that has that specific protein.
2. The **LAL** amino sequence (together with the following 14 aminos) does not appear in any of the other SA variant samples, but it does appear in the Wuhan variant, and in its vaccine.

We conclude that that protein and corresponding sample belong to the Wuhan variant, and will not be using it for the SA vaccine.

```
unique_sa_spike_proteins_without_coding_ambiguity.remove(weird_sa_spike_proteins_without_coding_ambiguity)
```

After removing the problematic sample we are left with the following **34** sequences (again divided by their spike protein):

```
sorted_samples = sorted(
    {protein: samples for protein, samples in unique_sa_spike_proteins.items() if protein in unique_sa_spike_proteins_without_c
    key=lambda x: len(x[1]), reverse=True)

for country, samples in sorted_samples:
    for start_idx in range(0, len(samples), 5):
        print(", ".join(samples[start_idx:start_idx + 5]))
    print()
```

```

```

```
MW796843.1

MW792756.1

MW621453.1
```

For the proteins we are using, we will use majority vote to decide what amino acid should be used for the vaccine.

This is done for 2 reasons:

1. If there's a sequencing error, we'll overcome it by using this method.
2. If it is not a sequencing error, it makes more sense to use the most common one for the vaccine.

```
print("On the left are the number of samples for that specific protein, at the bottom which amino to use in case of ambiguity")
print("-----------------------------------------------------------------------------------------------------------------------")

s1 = unique_sa_spike_proteins_without_coding_ambiguity[0]

maj_votes = []
for i in range(len(s1)):
    amino_maj_votes = defaultdict(int)
    for s in unique_sa_spike_proteins_without_coding_ambiguity:
        amino_maj_votes[s[i]] += len(unique_sa_spike_proteins[s])
    maj_votes.append(amino_maj_votes)

step = 136
for start_idx in range(0, len(s1), step):
    for s in unique_sa_spike_proteins_without_coding_ambiguity:
        print(f'{len(unique_sa_spike_proteins[s]):2}', s[start_idx:start_idx + step])

    s_parts = [s[start_idx:start_idx + step] for s in unique_sa_spike_proteins_without_coding_ambiguity]

```

So the spike protein we will use as the base for our vaccine is:

```
sa_vaccine_base = "".join([max(maj_vote, key=maj_vote.get) for maj_vote in maj_votes])

step = 136

for start_idx in range(0, len(sa_vaccine_base), step):
    print(sa_vaccine_base[start_idx:start_idx + step])
```

```

```

We also find the majority vote on the nucleotide level (among the proteins that agreed with the majority vote on the amino level).

```
# # Sample to data (including nucleotides)
# sa_spike_proteins.keys()

# # Protein to sample
# unique_sa_spike_proteins.keys()

# # Proteins analyzed
# unique_sa_spike_proteins_without_coding_ambiguity

sa_vaccine_base_nts = ""

for amino_idx, amino in enumerate(sa_vaccine_base):
    codons_for_amino = defaultdict(int)

    for protein in unique_sa_spike_proteins_without_coding_ambiguity:
        if protein[amino_idx] == amino:
            for sample_id_with_protein in unique_sa_spike_proteins[protein]:
                codon_for_amino_in_sample = sa_spike_proteins[sample_id_with_protein]['Nucleotide Seq'][amino_idx * 3:(amino_id
                codons_for_amino[codon_for_amino_in_sample] += 1

    selected_codon = max(codons_for_amino, key=codons_for_amino.get)
    sa_vaccine_base_nts += selected_codon
```

Yaniv Erlich
11:20 PM, May 12

Very nice work and correct!

Quick detour:

How do the proteins that were discarded because of sequencing ambiguities look, and how do these affect the result?

```
s1 = culled_sa_spike_proteins[0]

step = 136
for start_idx in range(0, len(s1), step):
    for s in culled_sa_spike_proteins:
        print(s[start_idx:start_idx + step])
```

```
    s_parts = [s[start_idx:start_idx + step] for s in culled_sa_spike_proteins]
    s_is = [set([s_part[i] for s_part in s_parts]) for i in range(len(s_parts[0]))]
    comparison = [' ' if len(s_i) == 1 else '^' for s_i in s_is]
    print("".join(comparison))
```

```

```

We see that at least some of the proteins discarded, most probably belong to the Wuhan variant (are longer by 3 amino acids, that can probably be attributed to the extra **LAL** amino chain that the Wuhan variant has when compared to the SA variant).

Let's see what result we'd have got, had we not dropped all the sequences with sequencing ambiguities, and instead just dropped only those that are longer by 3 aminos and probably belong to the SA variant:

```
wuhan_length = len(sa_spike_proteins[unique_sa_spike_proteins[weird_sa_spike_proteins_without_coding_ambiguity][0]]['Amino Seq'
```

```
# Histogram proteins explain how many samples each.
number_of_samples_per_unique_sa_spike_protein_hist = defaultdict(int)

# Unique spike proteins that don't contain coding ambiguity (that is marked by a non existing 'X' amino).
unique_sa_spike_proteins_without_coding_ambiguity = []
culled_sa_spike_proteins = []

for unique_sa_spike_protein in unique_sa_spike_proteins:
    number_of_samples_per_unique_sa_spike_protein_hist[len(unique_sa_spike_proteins[unique_sa_spike_protein])] += 1

    # According to: https://www.genome.jp/kegg/catalog/codes1.html

    if len(unique_sa_spike_protein) != wuhan_length:
        unique_sa_spike_proteins_without_coding_ambiguity.append(unique_sa_spike_protein)
    else:
        culled_sa_spike_proteins.append(unique_sa_spike_protein)
```

```
number_of_samples_per_unique_sa_spike_protein_hist
```

```
defaultdict(int, {1: 26, 2: 3, 3: 2, 8: 1, 18: 1})
```

```
len(unique_sa_spike_proteins), len(unique_sa_spike_proteins_without_coding_ambiguity)
```

```
(33, 27)
```

The numbers we found here are different, but that makes sense as every sample which has sequencing ambiguities will have a different protein than all the rest of the samples (unless the ambiguities are in exactly the same places, in which case several samples might be explained by a single protein).

In this case, the following samples **55** samples are used (divided by their spike proteins):

```
sorted_samples = sorted(
    {protein: samples for protein, samples in unique_sa_spike_proteins.items() if protein in unique_sa_spike_proteins_without_c
    key=lambda x: len(x[1]), reverse=True)

for country, samples in sorted_samples:
    for start_idx in range(0, len(samples), 5):
        print(", ".join(samples[start_idx:start_idx + 5]))
    print()
```

```

Let's look at how different the amino sequences are now:

```
s1 = unique_sa_spike_proteins_without_coding_ambiguity[0]

step = 136
for start_idx in range(0, len(s1), step):
    for s in unique_sa_spike_proteins_without_coding_ambiguity:
        print(s[start_idx:start_idx + step])

    s_parts = [s[start_idx:start_idx + step] for s in unique_sa_spike_proteins_without_coding_ambiguity]
    s_is = [set([s_part[i] for s_part in s_parts]) for i in range(len(s_parts[0]))]
    comparison = [' ' if len(s_i) == 1 else '^' for s_i in s_is]
    print("".join(comparison))
```

```

```

All the proteins look very similar, except (mostly) for the places with sequencing ambiguities.

For the proteins we are using, we will again use majority vote to decide what amino acid should be used for the vaccine, however ignore the "voters" that are ambiguous (per amino acid).

```
print("On the left are the number of samples for that specific protein, at the bottom which amino to use in case of ambiguity")
print("-----------------------------------------------------------------------------------------------------------------------")

s1 = unique_sa_spike_proteins_without_coding_ambiguity[0]

maj_votes = []
for i in range(len(s1)):
    amino_maj_votes = defaultdict(int)
    for s in unique_sa_spike_proteins_without_coding_ambiguity:
        if s[i] not in 'XBZJ':
            amino_maj_votes[s[i]] += len(unique_sa_spike_proteins[s])
    maj_votes.append(amino_maj_votes)

step = 136
for start_idx in range(0, len(s1), step):
    for s in unique_sa_spike_proteins_without_coding_ambiguity:
        print(f'{len(unique_sa_spike_proteins[s]):2}', s[start_idx:start_idx + step])

    s_parts = [s[start_idx:start_idx + step] for s in unique_sa_spike_proteins_without_coding_ambiguity]
    s_is = [[s_part[i] for s_part in s_parts] for i in range(len(s_parts[0]))]

 1 VMVTIMLCCMTSCCSCLKGCCSCGSCCKFDEDDSEPVLKGVKLHYT
 1 VMVTIMLCCMTSCCSCLKGCCSCGSCCKFDEDDSEPVLKGVKLHYT
 1 VMVTIMLCCMTSCCSCLKGCCSCGSCCKFDEDDSEPVLKGVKLHYT
 1 VMVTIMLCCMTSCCSCLKGCCSCGSCCKFDEDDSEPVLKGVKLHYT
 1 VMVTIMLCCMTSCCSCLKGCCSCGSCCKFDEDDSEPVLKGVKLHYT
 1 VMVTIMLCCMTSCCSCLKGCCSCGSCCKFDEDDSEPVLKGVKLHYT
```

So the spike protein we will use as the base for our vaccine is:

```
sa_vaccine_base_with_ambiguous = "".join([max(maj_vote, key=maj_vote.get) for maj_vote in maj_votes])
```

```
sa_vaccine_base_with_ambiguous == sa_vaccine_base
```

```
True
```

Now do the same on the nucleotide level (again among the proteins that agreed with the majority vote on the amino level but ignoring sequencing ambiguities).

```
sa_vaccine_base_nts_with_ambiguous = ""

for amino_idx, amino in enumerate(sa_vaccine_base):
    codons_for_amino = defaultdict(int)

    for protein in unique_sa_spike_proteins_without_coding_ambiguity:
        if protein[amino_idx] == amino and protein[amino_idx] not in 'XBZJ':
            for sample_id_with_protein in unique_sa_spike_proteins[protein]:
                codon_for_amino_in_sample = sa_spike_proteins[sample_id_with_protein]['Nucleotide Seq'][amino_idx * 3:(amino_id
                codons_for_amino[codon_for_amino_in_sample] += 1

    selected_codon = max(codons_for_amino, key=codons_for_amino.get)
    sa_vaccine_base_nts_with_ambiguous += selected_codon
```

```
sa_vaccine_base_nts_with_ambiguous == sa_vaccine_base_nts
```

```
True
```

And so we found that even had we used the samples discarded because of sequencing ambiguities, but not using the specific places that were actually ambiguous, we would have got the same result, on both the amino and the nucleotide levels.

End of detour

18

Use everything you learned so far, including the look up table of Pfizer and the addition of special nucleotides to design a South African mRNA vaccine. Don't forget the add the 5'UTR and 3'UTR. Report the vaccine sequence.

```
vaccines_data[company_names[0]]
```

```
{'Amino Seq': Seq('MFVFLVLLPLVSSQCVNLTTRTQLPPAYTNSFTRGVYYPDKVFRSSVLHSTQDL...HYT'),
 'End Codon': 'UGA',
 'End Codon Index': 3873,
 'Nucleotide Seq': 'AUGUUCGUGUUCCUGGUGCUGCUGCCUCUGGUGUCCAGCCAGUGUGUGAACCUGACCACCAGAACACAGCUGCCUCCAGCCUACACCAACAGCUUUACCAGAGGCGUGU
 'Start Codon Index': 54}
```

```
len(vaccines_data[company_names[0]]['Amino Seq']), len(sa_vaccine_base),
```

```
(1273, 1270)
```

We see that the length of the Pfizer Wuhan vaccine's spike protein is different than that of the SA variant's.

Let's compare the spike proteins:

```
print('Vac: Pfizer vaccine  -  Vir: SA variant virus\n==========================================================================\n')

step = 68
for start_idx in range(0, len(vaccines_data[company_names[0]]['Amino Seq']), step):
    try:
        vac_part = vaccines_data[company_names[0]]['Amino Seq'][start_idx:start_idx + step]
        vir_part = sa_vaccine_base[start_idx:start_idx + step]

        print('Vac:', vac_part)
        print('Vir:', vir_part)
        print('    ', "".join([' ' if vac_part[i] == vir_part[i] else '^' for i in range(len(vac_part))]))
    # We ignore exceptions created by index out of bound.
    except IndexError:
        pass
```

```

```

Now that we have a spike protein comparable to that of the vaccine (and by that also to that of the Wuhan variant that is only different on 2 amino acids vs the vaccine), we will construct the vaccine for the SA variant using the following rules:

1. For every amino acid that we see both in the existing vaccine and in the SA virus variant, we will use the vaccine's codon.
2. For amino acids that are different between them, we will use a codon from the mapping table we created earlier, by the same distribution of target codons found there (trying to keep an overall GC content similar to that of the vaccine).
3. Amino acids that are "missing" in the SA variant will be ignored.
4. For the 2 amino acids that are different between the existing vaccine and the Wuhan variant, we will use the existing vaccine's codons.
5. We will use a UGA end codon (of the vaccine) instead of the UAA codon that the different virus variants have.
6. We will add the 5', and 3' UTRs of the vaccine.

The overarching logic behind these rules is that the Pfizer vaccine amino changes vs the Wuhan spike protein are intentional, and so take precedence (there are 2 such instances), but everywhere else the vaccine should be identical to the virus (and so we'll use the SA variant virus' spike amino there).

On the codon level, the codon of the existing Pfizer vaccine should be used, unless the SA variant has a different amino than the vaccine, in which case we should use a codon for the amino based on the LUT we created earlier from virus codons to vaccine codons (again, except for the 2 intentional changes of the vaccine vs the virus, where we will use the vaccine's codons as well).

```
vir_codons_that_need_encoding = []

for start_idx in range(len(vaccines_data[company_names[0]]['Amino Seq'])):
    vac_part = vaccines_data[company_names[0]]['Amino Seq'][start_idx]
    vir_part = modified_sa_vaccine_base_amino[start_idx]

    if vac_part!= vir_part and vir_part != ' ':
        vir_codons_that_need_encoding.append(modified_sa_vaccine_base_codon[start_idx * 3:(start_idx + 1)* 3])

vir_codons_that_need_encoding
```

```
['GCU', 'GGU', 'AAU', 'AAA', 'UAU', 'GGU', 'GUA', 'AAA', 'GUU']
```

```
for vir_codons_that_need_encoding in vir_codons_that_need_encoding:
    print(vir_codons_that_need_encoding, '-->', vir_to_vac_codons_map[vir_codons_that_need_encoding])
```

```

            else:
                sa_vaccine += sa_to_vac_map[modified_sa_vaccine_base_codon[start_idx * 3:(start_idx + 1)* 3]]
```

Let's check the GC content of the new vaccine's spike protein:

```
f'New vaccine (spike protein) GC content is: {GC(sa_vaccine):.2f}%.'
```

```
'New vaccine (spike protein) GC content is: 57.06%.'
```

The GC content is higher than the vaccine, so we will lower it by changing some of the codons in the mapping, as allowed by the mapping.

We tried lowering GC content by 3 nucleotides, but that resulted in a GC content of 56.98% which is too low.

We settled on changing the GC content by only 2 nucleotides, making the GC content of the new vaccine, slightly higher than that of the Pfizer vaccine (57.01%), working under the assumption that if the GC content can't be kept - slightly higher is better than slightly lower.

```
# This is the mapping we will use (when needed):
sa_to_vac_map = {
       # This is allowed by the mapping we have, so we won't increase GC content
       'GCU': 'GCU',

    # We have this one twice, but that's still not enough to select different target codons (according to the distribution above
    'GGU': 'GGC',

       # When we tried to not change this as well (also allowed by the mapping we have), we got a GC content of 56.98%.
       'AAU': 'AAC',

    # We have this one twice as well, but same as above
    'AAA': 'AAG',

       # This is also allowed by the mapping we have, so we won't increase GC content again
      'UAU': 'UAU',

    'GUA': 'GUG',
    'GUU': 'GUG'
}
```

```
sa_vaccine = ""

for start_idx in range(len(vaccines_data[company_names[0]]['Amino Seq'])):
    vac_part = vaccines_data[company_names[0]]['Amino Seq'][start_idx]
    wuh_part = wuhan_sars_cov_2_data['Amino Seq'][start_idx]
    sav_part = modified_sa_vaccine_base_amino[start_idx]

    if wuh_part != vac_part:
        sa_vaccine += vaccines_data[company_names[0]]['Nucleotide Seq'][start_idx * 3:(start_idx + 1)* 3]
    else:
        if vac_part == sav_part:
            sa_vaccine += vaccines_data[company_names[0]]['Nucleotide Seq'][start_idx * 3:(start_idx + 1)* 3]
        else:
            if sav_part == ' ':
                continue
            else:
                sa_vaccine += sa_to_vac_map[modified_sa_vaccine_base_codon[start_idx * 3:(start_idx + 1)* 3]]

f'New vaccine (spike protein) GC content is: {GC(sa_vaccine):.2f}%.'
```

```
'New vaccine (spike protein) GC content is: 57.01%.'
```

Checking that the new SA variant vaccine spike has the same structure as the SA variant virus on the amino level.

```
translated_sa_vaccine_spike = Seq.Seq(sa_vaccine).translate()
vaccine_base_amino_no_spaces = modified_sa_vaccine_base_amino.replace(' ', '')

print('Vac: New vaccine based on SA variant  -  Vir: SA variant virus\n============================================================')

step = 68
for start_idx in range(0, len(vaccines_data[company_names[0]]['Amino Seq']), step):
    vac_part = translated_sa_vaccine_spike[start_idx:start_idx + step]
    vir_part = vaccine_base_amino_no_spaces[start_idx:start_idx + step]

    print('Vac:', vac_part)
    print('Vir:', vir_part)
    print('    ', "".join([' ' if vac_part[i] == vir_part[i] else '^' for i in range(len(vac_part))]))
```

```

Compare the spikes of the Pfizer vaccine and the new SA variant vaccine we created (we want to see the same vaccine, except for the differences that stem from the differences between the two virus variants):

```
inconsistency_start = modified_sa_vaccine_base_amino.find('HRSYLTPGDSSSGWTAGAAAYYVGYLQPRTF')

translated_sa_vaccine_spike = Seq.Seq(sa_vaccine).translate()
translated_modified_sa_vaccine_spike = f"{translated_sa_vaccine_spike[:inconsistency_start - 3]}   {translated_sa_vaccine_spike

print('VacS: New vaccine based on SA variant  -  VacP: Pfizer vaccine\n============================================================

step = 68
for start_idx in range(0, len(vaccines_data[company_names[0]]['Amino Seq']), step):
    vacs_part = translated_modified_sa_vaccine_spike[start_idx:start_idx + step]
    vacp_part = vaccines_data[company_names[0]]['Amino Seq'][start_idx:start_idx + step]

    print('VacS:', vacs_part)
    print('VacP:', vacp_part)
    print('     ', "".join([' ' if vacs_part[i] == vacp_part[i] else '^' for i in range(len(vacs_part))]))
```

```
VacS: New vaccine based on SA variant  -  VacP: Pfizer vaccine

(a possibly) Contradictory finding

We also found a paper by SA researchers (et al.): https://www.medrxiv.org/content/10.1101/2020.12.21.20248640v1.full-text , that specifically discusses the spike protein mutations relevant to the SA variant.

The researchers discuss a total of 9 mutations, the most distinguishing of which is **E484K** (as it was found present in less than 0.02% of the samples outside of SA).

They also divide the 9 mutations into 2 groups:

- 6 that were present since the first sampling of the SA variant on 2020-10-15: **D614G**, **D80A**, **D215G**, **E484K**, **N501Y**, **A701V**.
- 3 that appeared by end of 2020-11: **L18F**, **R246I**, **K417N**.

Furthermore, the **LAL** sequence we found to be missing in our classification of the proteins is also mentioned in the paper (as **L242_244L**), however it is still debated due to a different mutation (at least at the time of the paper's publishing - 2020-12-22).

We explore the samples and the specified mutations.

Checking if there are any samples that contain all the mutations:

```
mutations = ['D614G', 'D80A', 'D215G', 'E484K', 'N501Y', 'A701V', 'L18F', 'R246I', 'K417N']

mutation_sites = [int(m[1:-1]) - 1 for m in mutations]
mutation_values = [m[-1:] for m in mutations]

[k for k, d in sa_spike_proteins.items() if all([d['Amino Seq'][mutation_site] == mutation_values[mutation_idx] for mutation_id
```

```
[]
```

No, but let's look at the samples, and see if they have sequncing ambiguities in the mutation sites:

```
mutations = ['D614G', 'D80A', 'D215G', 'E484K', 'N501Y', 'A701V', 'L18F', 'R246I', 'K417N']
mutation_sites = [int(m[1:-1]) - 1 for m in mutations]
mutation_values = [m[-1:] for m in mutations]
original_values = [m[:1] for m in mutations]

print('Original', original_values)
print('Expected', mutation_values)
[(k, [d['Amino Seq'][mutation_site] for mutation_site in mutation_sites]) for k, d in sa_spike_proteins.items()]
```

```

```

We see that:

- Only 9 samples have the highly distinguishing **E484K** mutation.
- The same 9 samples also have all 6 "early" mutations, and only 1 of the "later" mutations.
- There's only one sample with sequencing ambiguities, and it is contained within the same 9 samples.

Let's have a look at the similarity between the proteins of these samples:

```
sa_samples = [k for k, d in sa_spike_proteins.items() if d['Amino Seq'][mutation_sites[3]] == mutation_values[3]]
sa_proteins = [d['Amino Seq'] for k, d in sa_spike_proteins.items() if d['Amino Seq'][mutation_sites[3]] == mutation_values[3]]
```

```
s1 = sa_proteins[0]

step = 136
for start_idx in range(0, len(s1), step):
    for s in sa_proteins:
        print(s[start_idx:start_idx + step])
```

```
    s_parts = [s[start_idx:start_idx + step] for s in sa_proteins]
    s_is = [set([s_part[i] for s_part in s_parts]) for i in range(len(s_parts[0]))]
    comparison = [' ' if len(s_i) == 1 else '^' for s_i in s_is]
    print("".join(comparison))
```

```

```

1. It appears all proteins are identical, except for sequencing ambiguities.
2. Completely contradictory to our analysis, all samples either have the **LAL** amino sequence, or are as long as the Wuhan protein sequence (in which case the area covering the **LAL** sequence has at least partial sequencing ambiguities).
3. The only sequence without ambiguities is the first one.

```
sa_vaccine_base_paper = sa_proteins[0]
```

And again use majority vote to decide what the nucleotide level is:

```
sa_vaccine_base_nts_paper = ""

for amino_idx, _ in enumerate(sa_vaccine_base_paper):
    codons_for_amino = defaultdict(int)

    for protein in sa_proteins:
        if protein[amino_idx] not in 'XBZJ':
            for sample_id_with_protein in unique_sa_spike_proteins[protein]:
                codon_for_amino_in_sample = sa_spike_proteins[sample_id_with_protein]['Nucleotide Seq'][amino_idx * 3:(amino_id
                codons_for_amino[codon_for_amino_in_sample] += 1

    selected_codon = max(codons_for_amino, key=codons_for_amino.get)
    sa_vaccine_base_nts_paper += selected_codon
```

Basing a vaccine on this sequence however, is bound to give different results than what we found so far.

Let's explore this in the same way we created the previous vaccine:

```
print('Vir1: Previously found SA variant virus  -  Vir2: SA variant virus accoring to paper\n==================================
step = 68
for start_idx in range(0, len(vaccines_data[company_names[0]]['Amino Seq']), step):

    vir1_part = modified_sa_vaccine_base_amino[start_idx:start_idx + step]
    vir2_part = sa_vaccine_base_paper[start_idx:start_idx + step]

    print('Vir1:', vir1_part)
    print('Vir2:', vir2_part)
    print('     ', "".join([' ' if vir1_part[i] == vir2_part[i] else '^' for i in range(len(vir1_part))]))
```

```
Vir1: Previously found SA variant virus  -  Vir2: SA variant virus accoring to paper

Surprisingly, the spikes are identical on the amino level, except for the extra **LAL** sequence we used in the new vaccine.

Let's compare the nucleotide level:

```
print('VirPap: New spike based on paper  -  VirPrv: Previous spike we found\n==========================================================')

step = 102
for start_idx in range(0, len(modified_sa_vaccine_base_codon), step):
    virprv_part = modified_sa_vaccine_base_codon[start_idx:start_idx + step]
    virpap_part = sa_vaccine_base_nts_paper[start_idx:start_idx + step]

    print('VirPrv:', virprv_part)
    print('VirPap:', virpap_part)
    print('       ', "".join([' ' if virprv_part[i] == virpap_part[i] else '^' for i in range(len(virprv_part))]))
```

```
VirPap: New spike based on paper  -  VirPrv: Previous spike we found

```

Only one nucleotide's difference between the spike according to the paper, and the method we previously used.

And compare to the Pfizer vaccine:

```
print('Vac: Pfizer vaccine  -  Vir: SA variant virus\n==========================================================================\n')

step = 68
for start_idx in range(0, len(vaccines_data[company_names[0]]['Amino Seq']), step):

    vac_part = vaccines_data[company_names[0]]['Amino Seq'][start_idx:start_idx + step]
    vir_part = sa_vaccine_base_paper[start_idx:start_idx + step]

    print('Vac:', vac_part)
    print('Vir:', vir_part)
    print('    ', "".join([' ' if vac_part[i] == vir_part[i] else '^' for i in range(len(vac_part))]))
```

```

Codons that need encoding are the same as before:

```
vir_codons_that_need_encoding = []

for start_idx in range(len(vaccines_data[company_names[0]]['Amino Seq'])):
    vac_part = vaccines_data[company_names[0]]['Amino Seq'][start_idx]
    vir_part = sa_vaccine_base_paper[start_idx]

    if vac_part != vir_part:
        vir_codons_that_need_encoding.append(sa_vaccine_base_nts_paper[start_idx * 3:(start_idx + 1)* 3])

vir_codons_that_need_encoding
```

```
['GCU', 'GGU', 'AAU', 'AAA', 'UAU', 'GGU', 'GUA', 'AAA', 'GUU']
```

```
for vir_codons_that_need_encoding in vir_codons_that_need_encoding:
    print(vir_codons_that_need_encoding, '-->', vir_to_vac_codons_map[vir_codons_that_need_encoding])
```

```
GCU --> defaultdict(<class 'int'>, {'GCC': 35, 'GCU': 5, 'GCA': 2})
GGU --> defaultdict(<class 'int'>, {'GGC': 40, 'GGG': 1, 'GGA': 5, 'GGU': 1})
AAU --> defaultdict(<class 'int'>, {'AAC': 41, 'AAU': 13})
AAA --> defaultdict(<class 'int'>, {'AAG': 31, 'AAA': 6})
UAU --> defaultdict(<class 'int'>, {'UAC': 36, 'UAU': 4})
GGU --> defaultdict(<class 'int'>, {'GGC': 40, 'GGG': 1, 'GGA': 5, 'GGU': 1})
GUA --> defaultdict(<class 'int'>, {'GUG': 15})
AAA --> defaultdict(<class 'int'>, {'AAG': 31, 'AAA': 6})
GUU --> defaultdict(<class 'int'>, {'GUG': 41, 'GUC': 6})
```

```
# This is the mapping we will use (when needed):
sa_to_vac_map = {
    'GCU': 'GCC',

    # We have this one twice
    'GGU': 'GGC',

    'AAU': 'AAC',

    # We have this one twice as well
    'AAA': 'AAG',

    'UAU': 'UAC',
    'GUA': 'GUG',
    'GUU': 'GUG'
}
```

```
sa_vaccine_paper = ""

for start_idx in range(len(vaccines_data[company_names[0]]['Amino Seq'])):
    vac_part = vaccines_data[company_names[0]]['Amino Seq'][start_idx]
    wuh_part = wuhan_sars_cov_2_data['Amino Seq'][start_idx]
    sav_part = sa_vaccine_base_paper[start_idx]

    if wuh_part != vac_part:
        sa_vaccine_paper += vaccines_data[company_names[0]]['Nucleotide Seq'][start_idx * 3:(start_idx + 1)* 3]
    else:
        if vac_part == sav_part:
            sa_vaccine_paper += vaccines_data[company_names[0]]['Nucleotide Seq'][start_idx * 3:(start_idx + 1)* 3]
        else:
            sa_vaccine_paper += sa_to_vac_map[sa_spike_proteins[sa_samples[0]]['Nucleotide Seq'][start_idx * 3:(start_idx + 1)*
```

Let's check the GC content of the new vaccine's spike protein:

```
f'New vaccine (spike protein) GC content is: {GC(sa_vaccine_paper):.2f}%.'
```

```
'New vaccine (spike protein) GC content is: 57.11%.'
```

Again, the GC is too high, so we repeat the process of not encoding all codons to those with higher GC content:

```
sa_to_vac_map = {
       # This is allowed by the mapping we have, so we won't increase GC content
       'GCU': 'GCU',

       # This is allowed by the mapping we have, so we won't increase GC content
       # We have this one twice
       'GGU': 'GGA',

    # When we tried to not change this as well, we again got a GC content of 56.98%.
    'AAU': 'AAC',

    # We have this one twice as well, but same as above
    'AAA': 'AAG',

       # This is also allowed by the mapping we have, so we won't increase GC content again
      'UAU': 'UAU',

    'GUA': 'GUG',
    'GUU': 'GUG'
}

sa_vaccine_paper = ""

for start_idx in range(len(vaccines_data[company_names[0]]['Amino Seq'])):
    vac_part = vaccines_data[company_names[0]]['Amino Seq'][start_idx]
    wuh_part = wuhan_sars_cov_2_data['Amino Seq'][start_idx]
    sav_part = sa_vaccine_base_paper[start_idx]

    if wuh_part != vac_part:
        sa_vaccine_paper += vaccines_data[company_names[0]]['Nucleotide Seq'][start_idx * 3:(start_idx + 1)* 3]
    else:
        if vac_part == sav_part:
            sa_vaccine_paper += vaccines_data[company_names[0]]['Nucleotide Seq'][start_idx * 3:(start_idx + 1)* 3]
        else:
            sa_vaccine_paper += sa_to_vac_map[sa_spike_proteins[sa_samples[0]]['Nucleotide Seq'][start_idx * 3:(start_idx + 1)*

f'New vaccine (spike protein) GC content is: {GC(sa_vaccine_paper):.2f}%.'
```

```
'New vaccine (spike protein) GC content is: 57.00%.'
```

And again as before, we had to select between either having a GC content of 57%, or 56.98%, and chose the higher one.

Checking that the new SA variant vaccine spike has the same structure as the SA variant virus on the amino level.

```
translated_sa_vaccine_spike_paper = Seq.Seq(sa_vaccine_paper).translate()

print('Vac: New vaccine based on SA variant  -  Vir: SA variant virus\n============================================================')

step = 68
for start_idx in range(0, len(vaccines_data[company_names[0]]['Amino Seq']), step):
    vac_part = translated_sa_vaccine_spike_paper[start_idx:start_idx + step]
    vir_part = sa_vaccine_base_paper[start_idx:start_idx + step]

    print('Vac:', vac_part)
    print('Vir:', vir_part)
    print('    ', "".join([' ' if vac_part[i] == vir_part[i] else '^' for i in range(len(vac_part))]))
```

```

Compare the spikes of the Pfizer vaccine and the new SA variant vaccine we created (we want to see the same vaccine, except for the differences that stem from the differences between the two virus variants):

```
print('VacS: New vaccine based on SA variant  -  VacP: Pfizer vaccine\n============================================================')

step = 68
for start_idx in range(0, len(vaccines_data[company_names[0]]['Amino Seq']), step):
    vacs_part = translated_sa_vaccine_spike_paper[start_idx:start_idx + step]
    vacp_part = vaccines_data[company_names[0]]['Amino Seq'][start_idx:start_idx + step]

    print('VacS:', vacs_part)
    print('VacP:', vacp_part)
    print('     ', "".join([' ' if vacs_part[i] == vacp_part[i] else '^' for i in range(len(vacs_part))]))
```

```
VacS: New vaccine based on SA variant  -  VacP: Pfizer vaccine

Unsurprisingly, the vaccines are identical on the amino level, except for the extra **LAL** sequence we used in the new vaccine.

Let's compare the nucleotide level:

```
inconsistency_start = sa_vaccine.find('ACAGAAGCUACCUGACACCUGGCGAUAGCAGCAGCGGA')

modified_sa_vac = f"{sa_vaccine[:inconsistency_start]}         {sa_vaccine[inconsistency_start:]}"

print('VacPap: New vaccine based on paper  -  VacPrv: Previous vaccine we found\n==========================================================')

step = 102
for start_idx in range(0, len(modified_sa_vac), step):
    vacprv_part = modified_sa_vac[start_idx:start_idx + step]
    vacpap_part = sa_vaccine_paper[start_idx:start_idx + step]

    print('VacPrv:', vacprv_part)
    print('VacPap:', vacpap_part)
    print('       ', "".join([' ' if vacprv_part[i] == vacpap_part[i] else '^' for i in range(len(vacprv_part))]))
```

```
VacPap: New vaccine based on paper  -  VacPrv: Previous vaccine we found

As we used the codons of the Pfizer vacine to encode all amino acids that did not differ vs the Wuhan variant, the previous 1 nucleotide difference we saw between the vaccine bases dissappeard, and instead we have the following differences:

1. The **LAL** sequence that is not present in the old vaccine we developed,
2. The **GGU** to **GGA** encoding that we did on purpose on the new vaccine (to conform to the GC level of the original Wuhan vaccine), but ommitted from the previous vaccine we created.

Other than that the two vaccines are completely identical (as in addition to using the same codons for the amino acids - based on the Pfizer vaccine, we also used the same LUT we created).

This means that after we will add the end codon, and the 5' and 3' UTRs, these will remain the only differences between the two vaccines.

Yaniv Erlich

```
# Add missing parts to the SA vaccine (end codon will be taken together with the 3' UTR from the Pfizer vaccine):
sa_vac_final_paper = f"{vaccines_mRNA_seq[company_names[0]][:vaccines_data[company_names[0]]['Start Codon Index']]}{sa_vaccine_
```

```
step = 136

for start_idx in range(0, len(sa_vac_final_paper), step):
    print(sa_vac_final_paper[start_idx:start_idx + step])
```

Conclusions for this section

Despite the fact that we based this vaccine on completely different samples than the previous one we created (all previous samples were shorter by 3 amino acids), we still got exactly the same vaccine for the SA variant, with the only differences being either the extra/missing **LAL** amino sequence, or the ones introduced by us.

The meaning of this is that all the proteins we analyzed in all 3 phases above (looking only at sequences without sequencing errors, looking at all sequences as long as these have the missing **LAL** amino sequence, or based on the

11:22 PM, May 12

Correct! amazing job.

mutations described in the paper) are identical (down to the **LAL** sequence and sequencing ambiguities), and that the only difference between them is on the nucleotide level (we do not notice this in the comparison above, as the codons used are taken from the Pfizer vaccine).

Conclusions

1. We started off by familiarizing ourselves with the Wuhan variant of the Covid19 virus and the Pfizer vaccine for it, on both the nucleotide and amino acids levels. As part of this process we found:
    1. That the vaccine's spike protein differs from the virus' on only 2 amino acids, that are in charge of making the physical form of the protein less prone to change before it contacts a host's cell.
    2. That the GC content of the vaccine is much higher than that of the virus, in order to weaken the virus.
    3. That a LUT of sorts exists between the codons of the vaccine and those of the virus, which explains the difference in the GC content between them.
2. We continued to trying to develop a vaccine for the SA variant. This included the following steps:
    1. First we tried to identify samples belonging to the SA variant (out of all the complete human samples available on NCBI). We did this by comparing known mutation sites and their surroundings.
    2. We then tried to cull these samples by searching for unmatching dates or countries of collection, but did not find any samples to cull. We did however cull samples which could not be properly translated from nucleotides to amino acids (which we added to the analysis separately, and eventually concluded would not affect the result).
    3. Later we tried to synthesize the SA variant virus' spike protein by comparing the proteins of the the different samples. This led us to cull another sample based on its similarity to the Wuhan variant's virus and vaccine spike protein.
    4. This allowed us to synthesize the SA variant virus's spike protein by using all the samples' spike protein (and using majority vote first on the amino then on the nucleotide levels in cases of disagreement).
    5. After that, we created a base for our new SA variant vaccine (the spike protein of the vaccine) by using the synthesised virus spike protein, and the aformentioned LUT between virus and vaccine codons.
    6. We finished by adding the end codon, and the 3' and 5' UTRs from the Pfizer vaccine for the Wuhan variant, and by that finished creating our vaccine.

7. In addition, we compared our initial findings - a vaccine based on the "shorter" **LAL** missing spike protein, to using samples that have the longer **LAL** included spike protein (based on a paper), and arrived at the conclusion that other than the **LAL** sequence itself, and 2 other nucleotide changes (that **we** introduced to keep the GC content similar to the original Pfizer vaccine), the vaccines would have turned out identical.
